

Jupiter: Solana's liquidity aggregator

PROBLEM & USERS

- **Problem:** liquidity is split across dozens of DEXs; best price needs routing and order splitting.
- **Users:** traders on jup.ag, plus wallets and apps via API (its Price API is used by most Solana wallets).
- **Why Solana:** multi-hop routes need many accounts in one atomic tx; cheap fees, ~400 ms blocks and lookup tables make that practical.
- **Competitors:** OKX DEX aggregator, DFlow, Titan; Drift (perps); trading bots.

4+
own programs: swap, limit orders, DCA, perps

0–50
bps platform fee per swap, by token pair

BUSINESS MODEL	
SOL ↔ stable	2 bps
Most tokens	10 bps
New tokens (< 24 h)	50 bps
Referral share · perps fees · API plans	+

Real on-chain programs, run by off-chain keepers

ON-CHAIN

Swap v6 JUP6Lkb...

Perps PERPHjG...

DCA DCA265Vj...

Limit v2 j1o2qRp...

JUP JUPyiwr...

JLP 27G8MtK...

DECODED MAINNET TXS

Swap RouteV2 → DEX CPI → TransferChecked

DCA keeper FlashFill → JUP6 route → Fulfill

Perps keeper pushes signed prices → refresh JLP value

OFF-CHAIN

- **Metis** routing engine + RFQ market makers
- **Keepers** that fill DCA, limit and perps requests
- Swap / Price / Tokens APIs with API keys
- Tx landing: high-stake validator, MEV protection

RISKS → IMPROVEMENTS

- **Upgradeable programs:** publish the multisig and timelock setup
- **Keeper dependence:** permissionless fills
- **Oracle risk** for perps and JLP holders
- **One API for the ecosystem:** an outage breaks many apps

Takeaway: the opposite of Phantom: rules live **on-chain**, execution depends on **off-chain** routing and keepers. For Mzia, the Swap + Price APIs enable voice "convert to USDT".
